META-BOA: Metabolomics data Balancing with Over-sampling Algorithms[Quick Start](#) [Data Format](#) [Troubleshooting](#) [Cite META-BOA](#)**Overview of META-BOA**

META-BOA (*METAbolomics data Balancing with Over-sampling Algorithms*) is a software solution for handling sample imbalance primarily for metabolomics and lipidomics datasets.

Class imbalance can greatly impede building of machine learning models and a number of methods have been devised for equalizing the number of samples in different classes by over-sampling minority class. META-BOA creates "synthetic" samples by implementing one of the following algorithms:

1. SMOTE: Synthetic minority over-sampling technique

SMOTE randomly generates new synthetic samples between the known minority class samples without replication (Chawla, et al., 2002).

2. BSMOTE: Borderline synthetic minority over-sampling technique

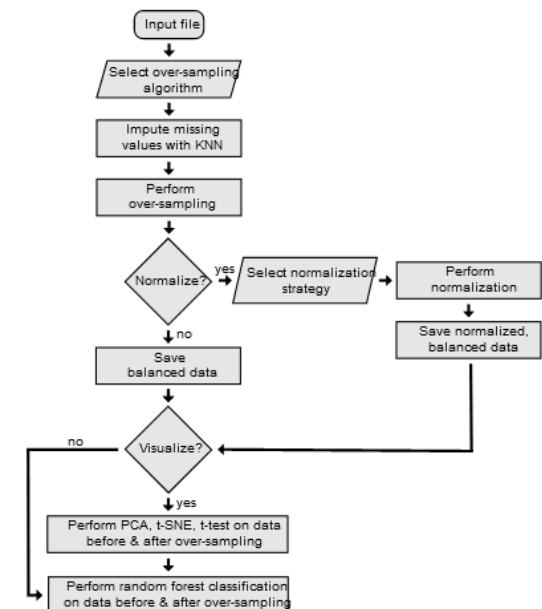

BSMOTE generates synthetic samples on the borderline between the majority and minority instances (Han, et al., 2005)

3. ADASYN: Adaptive synthetic

Distribution of synthetic samples created by ADASYN depends on the local distribution of samples in the minority class. ADASYN creates more samples in the neighborhood of minority samples that are in the vicinity of a larger number of the majority class cases (He, et al., 2008).

4. ROSE: Random over-sampling examples

ROSE is a bootstrap-based approach that creates synthetic samples in the neighbourhood of minority class features (Lunardon, et al., 2014).

META-BOA workflow.
